

Consider integer functions f from an n -element subset of \mathbb{N} such that no k of the points $\{(j_1, f(j_1)), \dots, (j_n, f(j_n))\}$ fall on a $k - 2$ -degree polynomial.

Figure 1: An example that shows that $a(4) = 4$. (Degree 0 polynomials are plotted in red, degree 1 in blue, and degree 2 in green.)

Question. What is $a(n)$, the least N such that there exists a function $f: \{1, 2, \dots, n\} \rightarrow \{1, 2, \dots, N\}$ with the above property?

Note. Trivially, $a(n)$ is bounded above by the function described in problem 23.

Related.

1. What is the least M such that there exists a subset $S \subset \{1, 2, \dots, M\}$ and a surjection $g: S \rightarrow \{1, 2, \dots, n\}$ with the aforementioned property?
2. How many such functions exist when N and M are minimized respectively?
